Introduction

The present study is based on significant progress in density functional theory (DFT), and associated software technology, which is sufficiently mature for the determination of dielectric response structure, and should actually provide complementary information to that obtained from experiment. Calculations are presented of ground and excited state resonance structure associated with clusters of water molecules that are randomly distributed and in liquid-phase using density functional theory (DFT) and its extension, time-dependent density functional theory (TD-DFT). Calculation of ground and excited state resonance structure using DFT and TD-DFT, respectively, can provide interpretation of absorption spectra with respect to molecular structure for excitation by electromagnetic waves at frequencies within the IR and UV ranges. The absorption spectrum of a molecular cluster consisting of a given number of water molecules should be associated with response features that are intermediate between that of isolated molecules and that of a bulk lattice. In principle, these absorption spectra should provide quantitative initial estimates of spectral response features that can be subsequently adjusted with respect to additional information such as laboratory measurements and other types of theory based calculations, or conversely, adapted as constraints for the inverse analysis of experimentally measured absorption spectra. A significant aspect of using DFT for the calculation of absorption spectra is that it adopts the perspective of computational physics, according to which a numerical simulation represents another source of “experimental” data.

Density functional theory has been successfully used to investigate the vibrational spectra of energetic materials in the form of single molecules and molecular crystals [1-9]. These calculations provide interpretation of absorption spectra with respect to molecular structure for various forms of materials, which can be encountered in various detection scenarios. In particular, the calculated absorption spectra of isolated molecules can help to identify intramolecular vibrational modes of various materials. A series of studies have focused on the general concept of constructing dielectric response functions using DFT for the purpose of quantitative simulation of explosives detection scenarios [9,10,11]. For these studies the DFT software GAUSSIAN09 (G09) was adopted [12]. As emphasized in these studies, the calculation of absorption spectra using DFT defines a general approach where dielectric response is estimated within the bounds of relatively well-defined adjustable parameters. Following this approach, permittivity functions are constructed using DFT calculated absorption spectra under the condition that the calculated resonance locations are fixed, while resonance widths and number densities are assumed adjustable with respect to additional information such as experimentally observed spectra or more advanced theory.

Previous studies have examined various properties of water molecules and their clusters [13-21]. The absorption spectrum of molecular clusters consisting of water molecules should be of significance for interpretation of absorption spectra associated with detection in practice. This follows in that most environments associated with detection in practice include the presence of water in one form or another. These forms can range from isolated molecules in gas phase, molecular clusters, adsorbed surface layers, droplets and interface regions in liquid phase, and ice. Absorption spectra of molecular clusters consisting of water represent a separate regime for dielectric response with respect to electromagnetic wave excitation. This regime should be better quantified for improved interpretation of absorption spectra associated with systems that include water clusters as components.

The organization of the subject areas presented are as follows. First, a general review of the elements of vibrational analysis using DFT that are relevant for the calculation of absorption spectra is presented. Second, calculations are presented of ground and excited state resonance structure of water clusters consisting of randomly-distributed molecules. Third, calculations are presented of ground and excited state resonance structure of liquid-phase water clusters. Fourth, calculations are presented of bond paths associated with equilibrium configurations of water clusters.

Calculation of Absorption Spectra using DFT

As in previous studies [9, 10, 11] the formal mathematical structure underlying DFT calculations, as well as the procedure for calculation of absorption spectra corresponding to vibrational states, is included here for purposes of completeness. The extension of DFT for the calculation of absorption spectra corresponding to electronic excitation states, which is the formalism of time-dependent density functional theory (TD-DFT), is described in reference [22].

The DFT software GAUSSIAN09 (G09) can be used to compute an approximation of the IR absorption spectrum of a molecule or molecules [23]. This program calculates vibrational frequencies by determining second derivatives of the energy with respect to the Cartesian nuclear coordinates, and then transforming to mass-weighted coordinates at a stationary point of the geometry. The IR absorption spectrum is obtained using density functional theory to compute the ground state electronic structure in the Born-Oppenheimer approximation using Kohn-Sham density functional theory [24-29]. GAUSSIAN uses specified orbital basis functions to describe the electronic wavefunctions and density. For a given set of nuclear positions, the calculation directly gives the electronic charge density of the molecule, the potential energy V , and the displacements in Cartesian coordinates of each atom. The procedure for vibrational analysis followed in GAUSSIAN is that described in Ref [23]. Reference [29] presents a fairly detailed review of this procedure. A brief description of this procedure is as follows.

The procedure followed by GAUSSIAN is based on the fact the vibrational spectrum depends on the Hessian matrix \mathbf{f}_{CART} , which is constructed using the second partial derivatives of the potential energy V with respect to displacements of the atoms in Cartesian coordinates. Accordingly, the elements of the $3N \times 3N$ matrix \mathbf{f}_{CART} are given by

$$f_{\text{CART}ij} = \left(\frac{\partial^2 V}{\partial \xi_i \partial \xi_j} \right)_0 \quad (1)$$

where $\{\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6, \dots, \xi_{3N}\} = \{\Delta x_1, \Delta y_1, \Delta z_1, \Delta x_2, \Delta y_2, \Delta z_2, \dots, \Delta z_N\}$, which are displacements in Cartesian coordinates, and N is the number of atoms. As discussed above, the zero subscript in Eq.(1) indicates that the derivatives are taken at the equilibrium positions of the atoms, and that the first derivatives are zero. Given the Hessian matrix defined by Eq.(1) the operations for calculation of the vibrational spectrum require that the Hessian matrix Eq.(1) be transformed to mass-weighted Cartesian coordinates according to the relation

$$f_{\text{MWC}ij} = \frac{f_{\text{CART}ij}}{\sqrt{m_i m_j}} = \left(\frac{\partial^2 V}{\partial q_i \partial q_j} \right)_0 \quad (2)$$

where $\{q_1, q_2, q_3, q_4, q_5, q_6, \dots, q_{3N}\} = \{\sqrt{m_1} \Delta x_1, \sqrt{m_1} \Delta y_1, \sqrt{m_1} \Delta z_1, \sqrt{m_2} \Delta x_2, \sqrt{m_2} \Delta y_2, \sqrt{m_2} \Delta z_2, \dots, \sqrt{m_N} \Delta z_N\}$ are the mass-weighted Cartesian coordinates. GAUSSIAN computes the energy second derivatives Eq.(2), thus computing the forces for displacement perturbations of each atom along each Cartesian direction. The first derivatives of the dipole moment with respect to atomic positions $\partial \vec{\mu} / \partial \xi_i$ are also computed. Each vibrational eigenmode leads to one peak in the absorption spectrum, at a frequency equal to the mode's eigenfrequency ν_{n0} . The absorption intensity corresponding to a particular eigenmode n whose eigenfrequency is ν_{n0} is given by

$$I_n = \frac{\pi}{3c} \left| \sum_{i=1}^{3N} \frac{\partial \vec{\mu}}{\partial \xi_i} l_{\text{CART}in} \right|^2, \quad (3)$$

where \mathbf{l}_{CART} is the matrix whose elements are the displacements of the atoms in Cartesian coordinates. The matrix \mathbf{l}_{CART} is determined by the following procedure. First,

$$\mathbf{I}_{\text{CART}} = \mathbf{M}\mathbf{I}_{\text{MWC}}, \quad (4)$$

where \mathbf{I}_{MWC} is the matrix whose elements are the displacements of the atoms in mass-weighted Cartesian coordinates and \mathbf{M} is a diagonal matrix defined by the elements

$$M_{ii} = \frac{1}{\sqrt{m_i}}. \quad (5)$$

Proceeding, \mathbf{I}_{MWC} is the matrix needed to diagonalize \mathbf{f}_{MWC} defined by Eq.(2) such that

$$(\mathbf{I}_{\text{MWC}})^T \mathbf{f}_{\text{MWC}} (\mathbf{I}_{\text{MWC}}) = \Lambda, \quad (6)$$

where Λ is the diagonal matrix with eigenvalues λ_i . The procedure for diagonalizing Eq.(6) consists of the operations

$$\mathbf{f}_{\text{INT}} = (\mathbf{D})^T \mathbf{f}_{\text{MWC}} (\mathbf{D}) \quad (7)$$

and

$$(\mathbf{L})^T \mathbf{f}_{\text{MWC}} (\mathbf{L}) = \Lambda, \quad (8)$$

where \mathbf{D} is a matrix transformation to coordinates where rotation and translation have been separated out and \mathbf{L} is the transformation matrix composed of eigenvectors calculated according to Eq.(8). The eigenfrequencies in units of (cm^{-1}) are calculated using the eigenvalues λ_n by the expression

$$\nu_{n0} = \frac{\sqrt{\lambda_n}}{2\pi c}, \quad (9)$$

where c is the speed of light. The elements of \mathbf{I}_{CART} are given by

$$l_{\text{CART}ki} = \sum_{j=1}^{3N} \frac{D_{kj} L_{ji}}{\sqrt{m_j}}, \quad (10)$$

where k , $i=1, \dots, 3N$, and the column vectors of these elements are the normal modes in Cartesian coordinates.

The intensity Eq.(3) must then be multiplied by the number density of molecules to give an absorption-line intensity in the non-interacting molecule approximation. It follows that the absorption spectrum calculated by GAUSSIAN is a sum of delta functions, whose line positions and coefficients correspond to the vibrational-transition frequencies and the absorption-line intensities, respectively. In principle, however, these spectral components must be broadened and shifted to account for anharmonic effects such as finite mode lifetimes and inter-mode couplings.

The DFT software GAUSSIAN09 (G09) can be used to compute an approximation of the UV absorption spectrum of a molecule or molecules by application of the formalism of time-dependent density functional theory (TD-DFT), which is described in reference [22].

Ground and Excited State Resonance Structure of Water Clusters Consisting of Randomly-Distributed Molecules

In this section are presented the results of computational investigations using DFT and TD-DFT concerning randomly-distributed water clusters of various size. These results include the relaxed or equilibrium configurations of water clusters ground-state oscillation frequencies and IR intensities, and oscillator strength as a function of excitation energy (within the UV range) for different geometries of

the interacting systems associated with stable structures, which are calculated by DFT and TD-DFT. For these calculations geometry optimization and vibrational analysis was effected using the DFT model B3LYP [30, 31] and basis function 6-311+G(d) [32, 33]. According to the specification of this basis function, (d) designates polarization functions having d functions for heavy atoms [34].

A graphical representation of molecular geometries of water clusters consisting of 2, 5, 12, 24 and 38 randomly-distributed molecules are shown in Figs. (1), (4), (7), (10) and (13), respectively. It is significant to note that the relative positions of the molecules associated with each of the molecular clusters is according to randomly selected positions of the water molecules prior to relaxation. The relaxed or equilibrium configurations of the water clusters consisting of 2, 5, 12, 24 and 38 randomly-distributed molecules are given in Tables 1, 4, 7, 10 and 13, respectively. The ground-state oscillation frequencies and IR intensities for the different molecular clusters, corresponding to their relaxed equilibrium configurations, are calculated by DFT according to the frozen phonon approximation. In the cases of water clusters consisting of 2, 5, 12, 24 and 38 randomly-distributed molecules, these values are given in Tables 2, 5, 8, 11 and 14, respectively. IR intensities as a function of frequency for the water clusters consisting of 2, 5, 12, 24 and 38 randomly-distributed molecules are shown in Figs. (2), (5), (8), (11) and (14), respectively.

Excitation energies and oscillator strengths of waters clusters of consisting of 2, 5, 12, 24 and 38 randomly-distributed molecules, after geometry optimization, which are calculated using TD-DFT, are given in Tables 3, 6, 9, 12 and 15. Correspondingly, the oscillator strength (UV intensity) as a function of excitation energy for the 2, 5, 12, 24 and 38 molecule water clusters are shown in Figs. (3), (6), (9), (12) and (15), respectively.

Ground and Excited State Resonance Structure of Liquid-Phase Water Clusters

In this section are presented the results of computational investigations using DFT and TD-DFT concerning liquid-phase water clusters of various size. These results include the relaxed or equilibrium configurations of water clusters ground-state oscillation frequencies and IR intensities, and oscillator strength as a function of excitation energy (within the UV range) for different geometries of the interacting systems associated with stable structures, which are calculated by DFT and TD-DFT. For these calculations geometry optimization and vibrational analysis was effected using the DFT model B3LYP [30, 31] and basis function 6-311+G(d) [32, 33]. According to the specification of this basis function, (d) designates polarization functions having d functions for heavy atoms [34]. The initial configuration of the liquid-phase clusters, prior to relaxation, was constructed using results of an 8 ps molecular dynamics simulations, which used model designations and parameters DFT/BLYP (code is CP2K, GTH pseudopotentials, DZVP basis, 280 eV cutoff), T=300 K, 0.5 fs time step, constant volume. The input to that simulation was a configuration from the end of a long (1 ns) flexible MM (potential was TIP3P) simulation with T=300 K and 0 pressure. The procedure of constructing the initial configuration of the liquid-phase clusters entailed cutting out clusters of whole water molecules which included all O atoms within some distance of a particular central O atom (distances are 2, 3, 4, 5, 6 Å).

A graphical representation of molecular geometries of liquid-phase water clusters consisting of 5, 12, 24 and 38 molecules are shown in Figs. (16), (19), (22) and (25), respectively. The relaxed or equilibrium configurations of the liquid-phase water clusters consisting of 5, 12, 24 and 38 molecules are given in Tables 16, 19, 22 and 25, respectively. The ground-state oscillation frequencies and IR intensities for the different molecular clusters, corresponding to their relaxed equilibrium configurations, are calculated by DFT according to the frozen phonon approximation. In the cases of liquid-phase water clusters consisting of 5, 12, 24 and 38 molecules, these values are given in Tables 17, 20, 23, and 26, respectively. IR intensities as a function of frequency for the liquid-phase water clusters consisting of 5, 12, 24 and 38 molecules are shown in Figs. (17), (20), (23) and (26), respectively.

Excitation energies and oscillator strengths of liquid-phase waters clusters of consisting of 5, 12, 24 and 38 molecules, after geometry optimization, which are calculated using TD-DFT, are given in Tables 18, 21, 24 and 27. Correspondingly, the oscillator strength (UV intensity) as a function of excitation energy for the 5, 12, 24 and 38 molecule water clusters are shown in Figs. (18), (21), (24) and (27), respectively.

Bond Paths For Equilibrium Configurations of Water Clusters

Presented in this section is an analysis of the electronic structure of water clusters in terms of the quantum topological property of electron density called the bond path. A bond path is the line along which the electron density is a maximum with respect to a neighboring line. Accordingly, if two atoms are bonded, their atomic volumes share a common interatomic surface, upon which there is a critical point where the gradient of the charge density is zero.

The theorem of Hohenberg & Kohn (HK) asserts that every quantum property of a molecular system is determined by the electron density, a mathematical object which is a function of the coordinates of only one particle at every local point in 3 dimensional space. This of course is vastly simpler than the wave function, an antisymmetric function of the coordinates of all N electrons in the molecular system, simultaneously occupying N different positions in space. The topological properties of the electron density allow an analysis which applies locally in the atomic space. Importantly, such a property is that of the bond path. This arises as follows. The full molecular electron density can be divided into its unique atomic components by the equation

$$\nabla\rho \cdot \bar{n} = 0 \quad (11)$$

where ρ is the charge density and \bar{n} is a unit vector normal to the surface. The surfaces over which this equation holds serve to divide the molecule into its component atoms each of which is encapsulated within a zero flux surface. The atoms so defined are individual quantum systems which satisfy the virial theorem. The properties of these atoms deliver the corresponding properties of the full molecule by simple summation of the atomic properties. The bond path is a unique trajectory between pairs of bonding atoms defined as that path in real space along which at every point the electron density is a local maximum. The bond path may lie along a straight line between atomic nuclei, but is more generally a curved path between a bonded pair. Importantly, and there has been found to this no exception, bonding attractions between atoms are universally characterized by a bond path. If atoms are bonded by any chemical mechanism whatever, be it covalent, ionic, hydrogen bonding, London dispersion, etcetera, where a bonding attraction exists, so too does a corresponding bond path indicative thereof. It is not always obvious which atoms have bonding interactions in a molecule, so the existence of or lack of a bond path in the density is the ultimate criterion which may be used to decide the question. On every bond path between bonding atoms there exists a mathematical critical point called the bond critical point, which defines the extremities of the electron densities belonging to a bonding pair of atoms. The magnitude of the electron density at the bond critical point is a direct measure of the strength of the bonding interaction in force between the atoms. The bigger the density at the bond critical point the bigger is the bond strength between the atomic pair connected by a bond path. In summary, one may say the importance of the bond path is that it defines a molecular graph and serves as a universal indicator of the existence of bonding interactions, the strength of which is numerically measured by the electron density at the bond path critical point. Further discussion of quantum theory concerning bond paths is given in reference [35].

Shown in Tables 28 and 29 are denumerations of the different types of critical points associated with the electron density and calculated bond paths, i.e., bond critical point (BCP), ring critical point (RCP) and cage critical point (CCP), the AIMQB atomic properties. Shown in Table 30 are nets charges on the atoms for the different molecular clusters, i.e., the AIMQB net charge of the atoms. The

calculation of bond paths was done using the software AIMALL [36].

Conclusion

The DFT and TD-DFT calculated absorption spectra given here provide two types of information for general analysis of dielectric response. These are the denumeration of ground and excited state resonance modes and estimates of molecular level dielectric response structure. The calculations of ground and excited state resonance structure associated with disordered and ordered clusters of water molecules using DFT and TD-DFT are meant to serve as reasonable estimates of molecular level response characteristics, providing interpretation of dielectric response features, for subsequent adjustment relative to experimental measurements and additional constraints based on molecular structure theory. With respect to spectroscopic methods for detection or monitoring of target molecules within various types of water environments, i.e., different types of detection strategies and their associated algorithms for post-processing of measurements, the calculated resonance spectra presented here serve the purpose of isolating spectral features for correlating with the presence of water clusters.

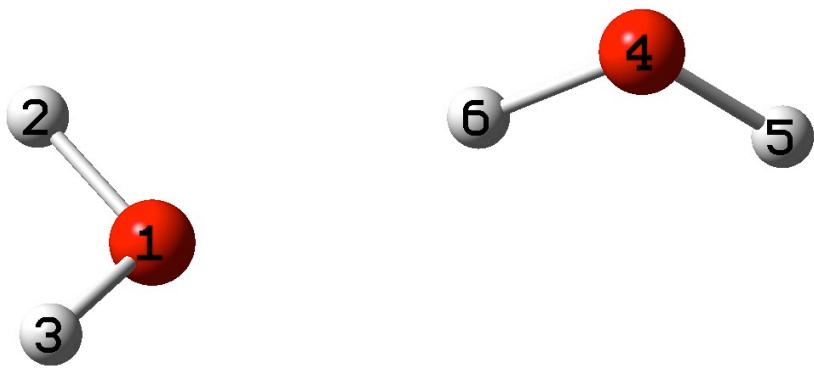

Figure 1. Molecular geometry of randomly-distributed water cluster consisting of 2 molecules, where relative location of atoms are given in Table 1.

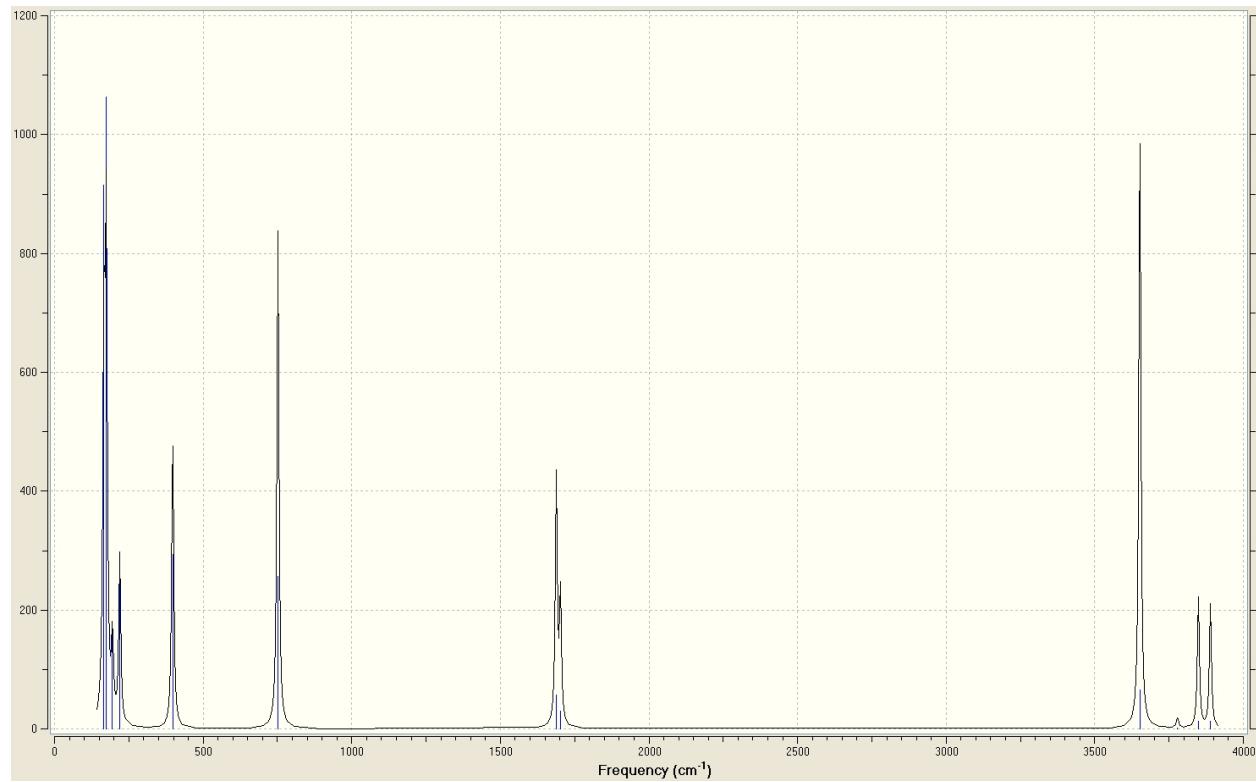

Figure 2. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for two-molecule randomly-distributed water cluster according to frozen phonon approximation.

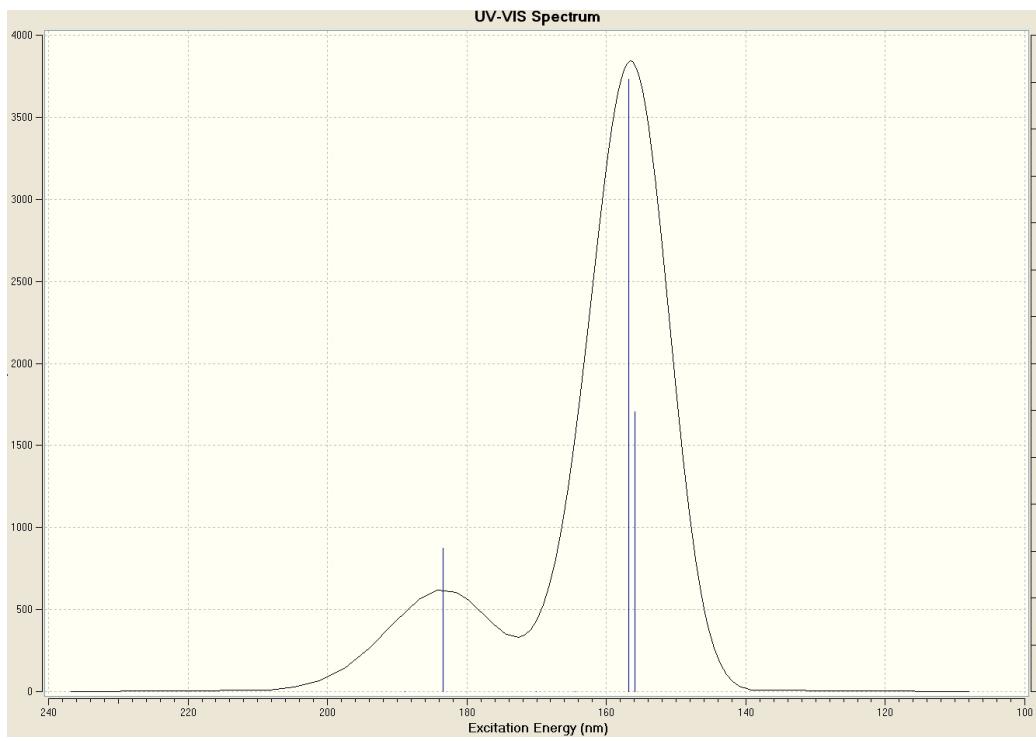

Figure 3. Oscillator strength as a function of excitation energy for two-molecule randomly-distributed water cluster calculated using TD-DFT.

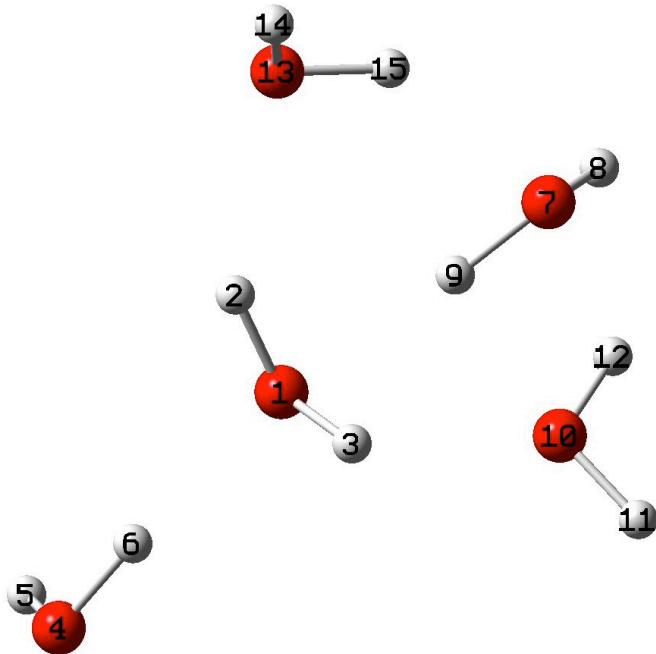

Figure 4. Molecular geometry of randomly-distributed water cluster consisting of 5 molecules, where relative location of atoms are given in Table 4.

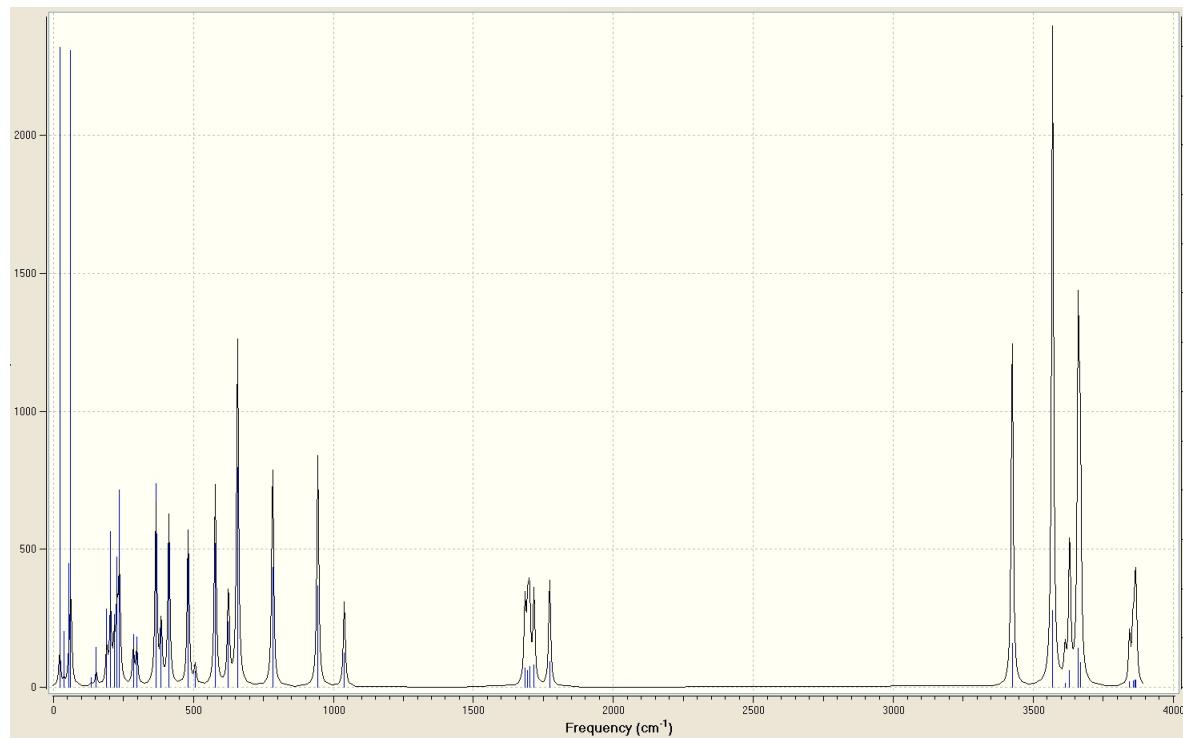

Figure 5. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for five-molecule randomly-distributed water cluster according to frozen phonon approximation.

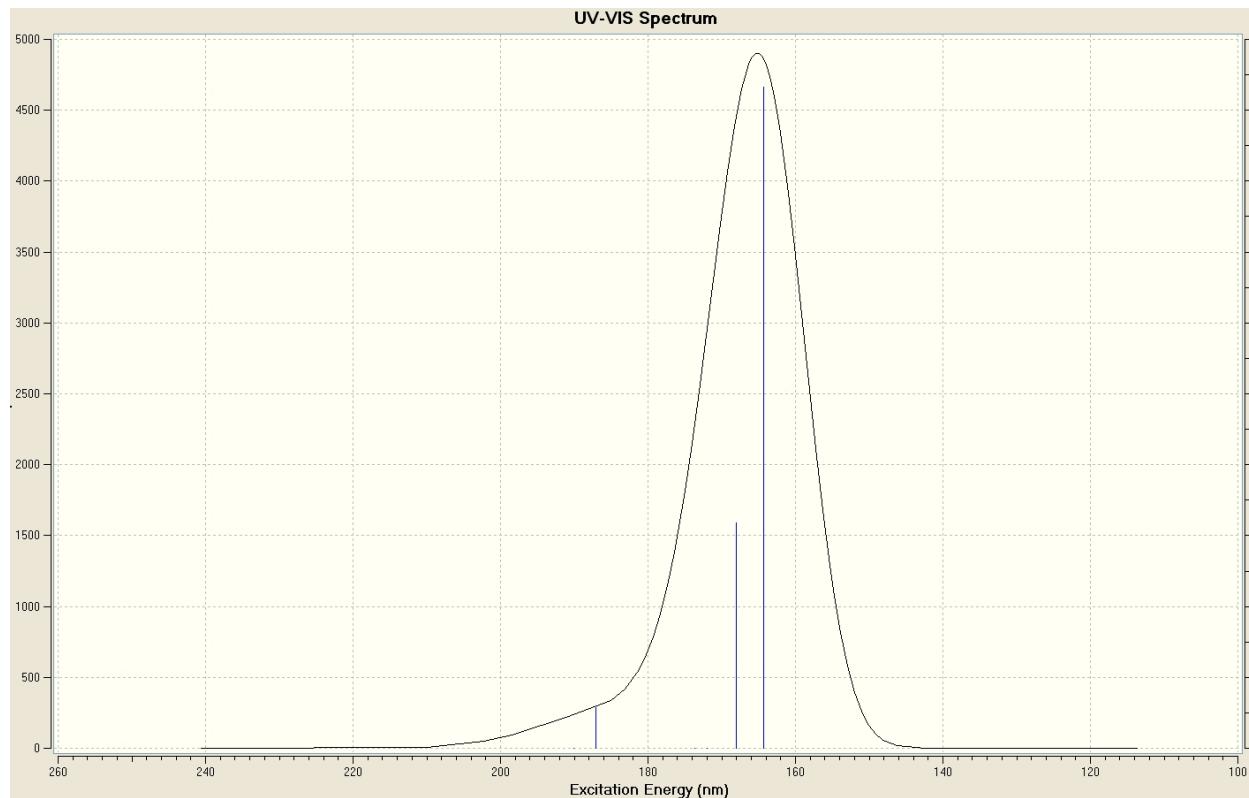

Figure 6. Oscillator strength as a function of excitation energy for five-molecule ($5\text{H}_2\text{O}$) randomly-distributed water cluster calculated using TD-DFT.

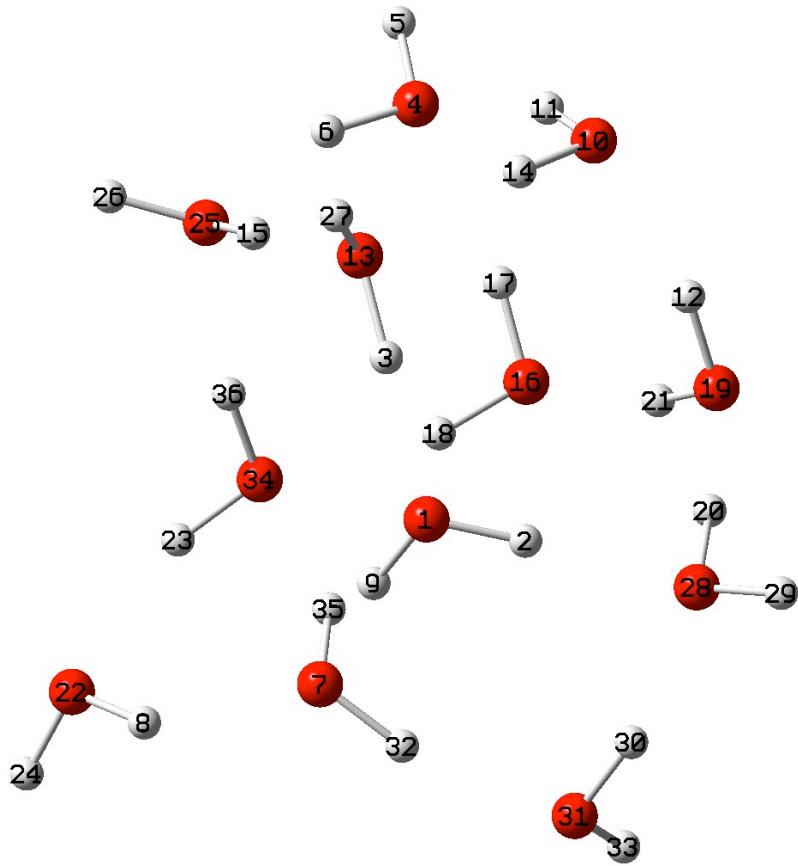

Figure 7. Molecular geometry of randomly-distributed water cluster consisting of 12 molecules, where relative location of atoms are given in Table 7.

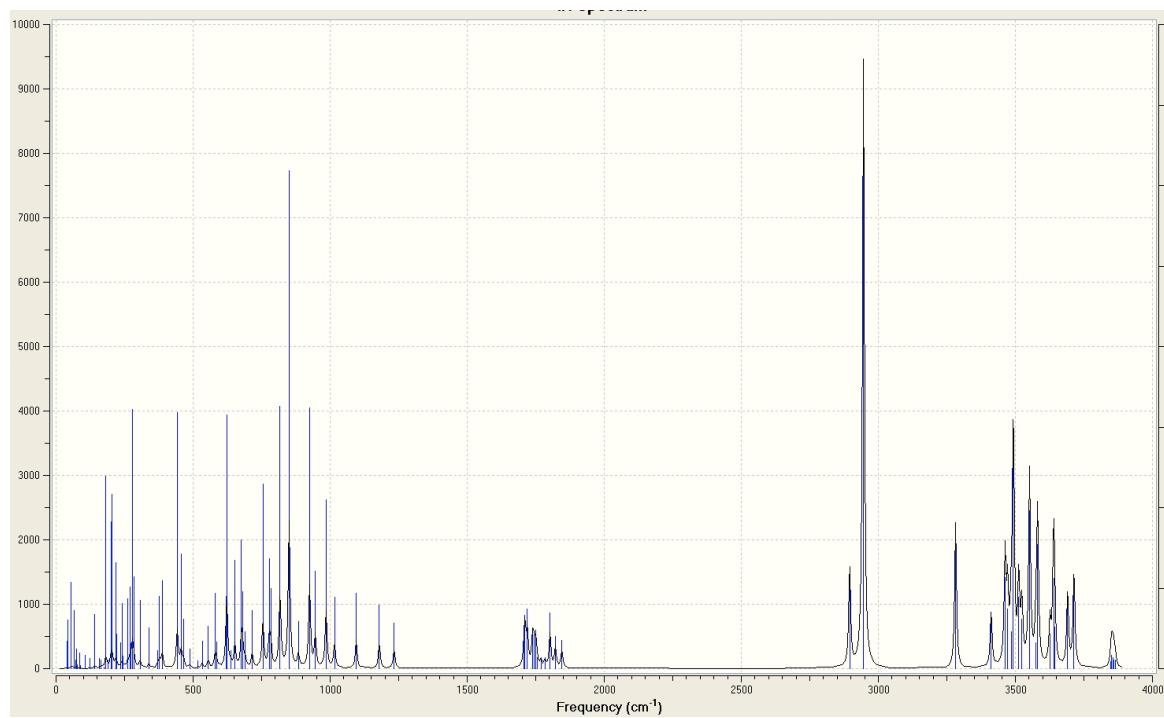

Figure 8. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for 12-molecule randomly-distributed water cluster according to frozen phonon approximation.

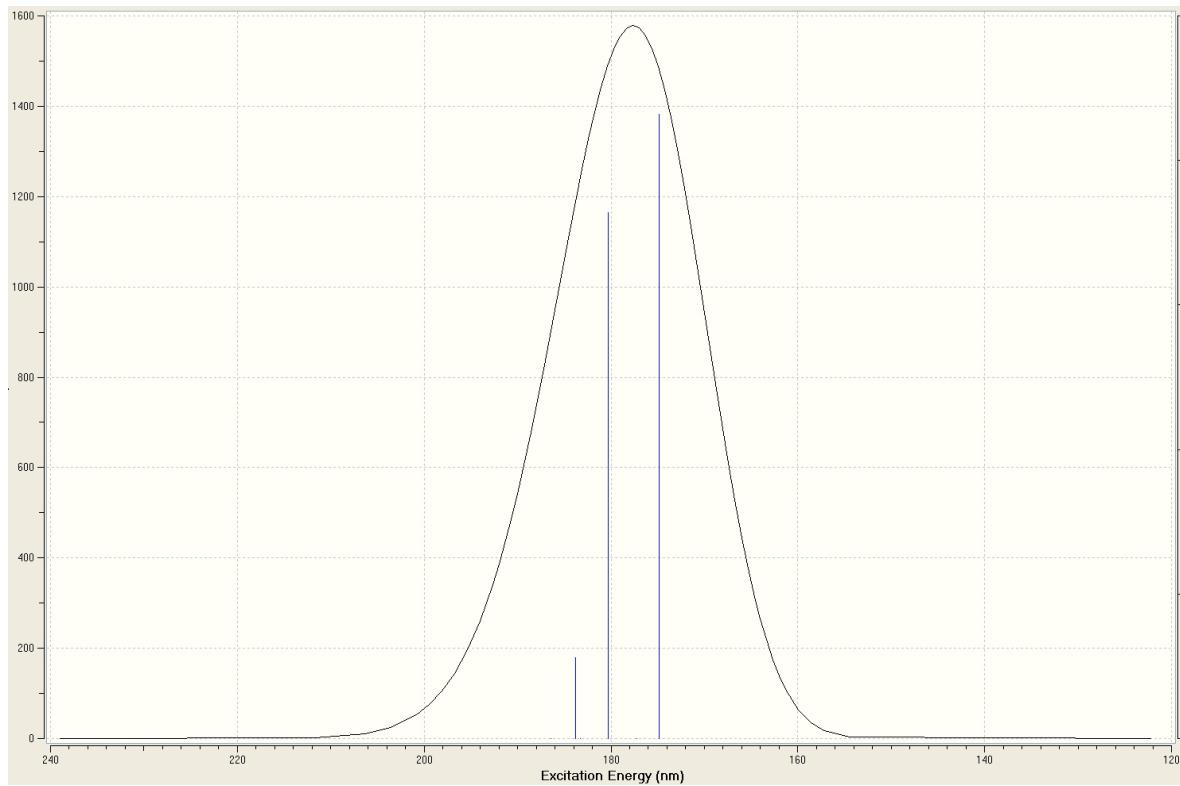

Figure 9. Oscillator strength as a function of excitation energy for 12-molecule (12H₂O) randomly-distributed water cluster calculated using TD-DFT.

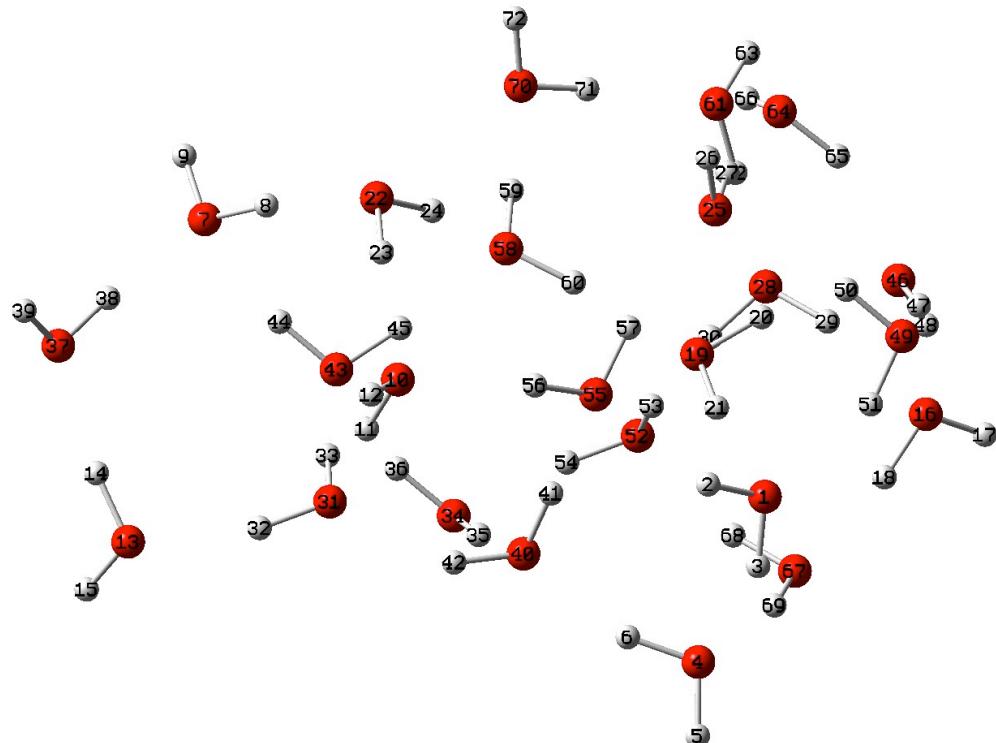

Figure 10. Molecular geometry of randomly-distributed water cluster consisting of 24 molecules, where relative location of atoms are given in Table 10.

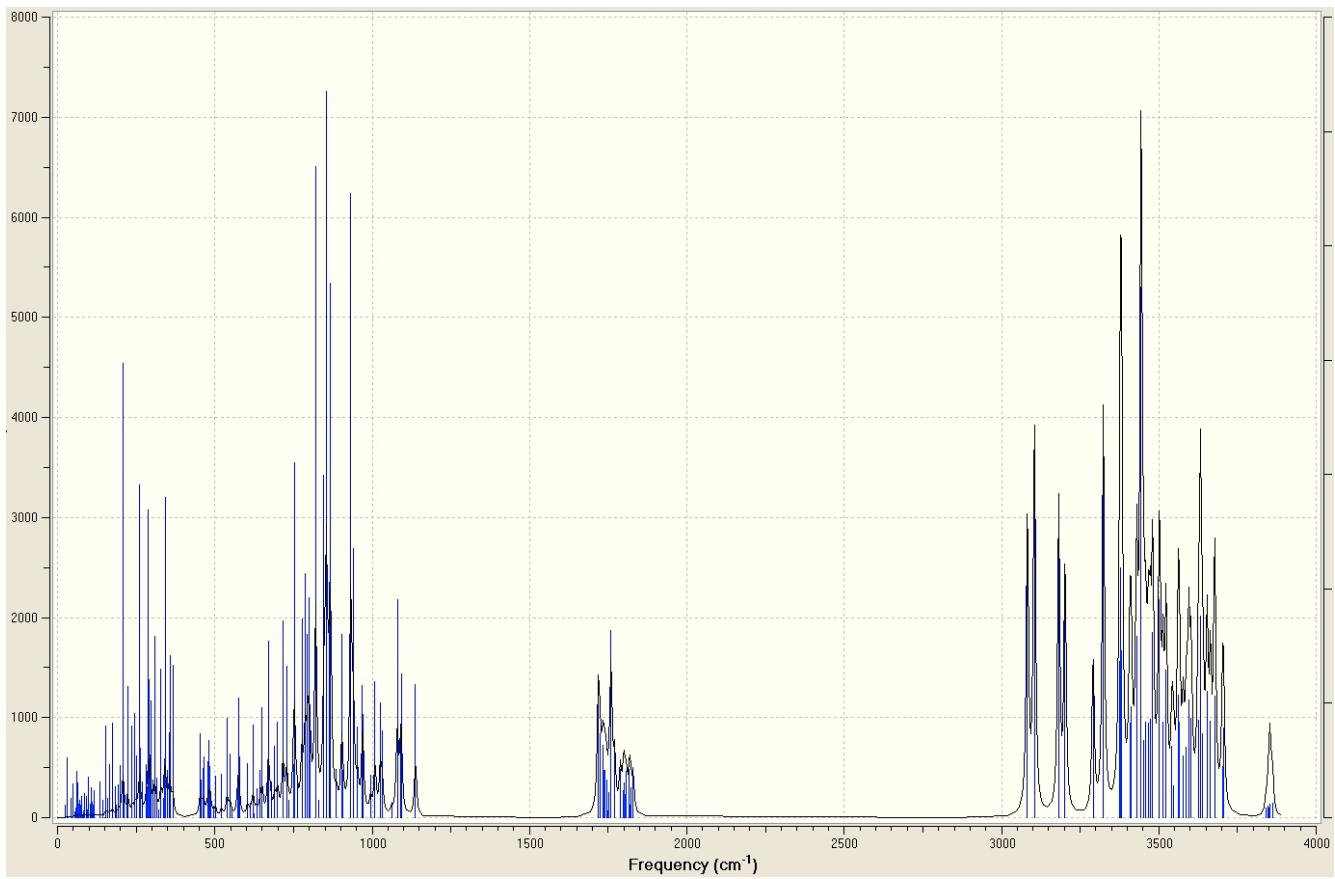

Figure 11. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for 24-molecule randomly-distributed water cluster according to frozen phonon approximation.

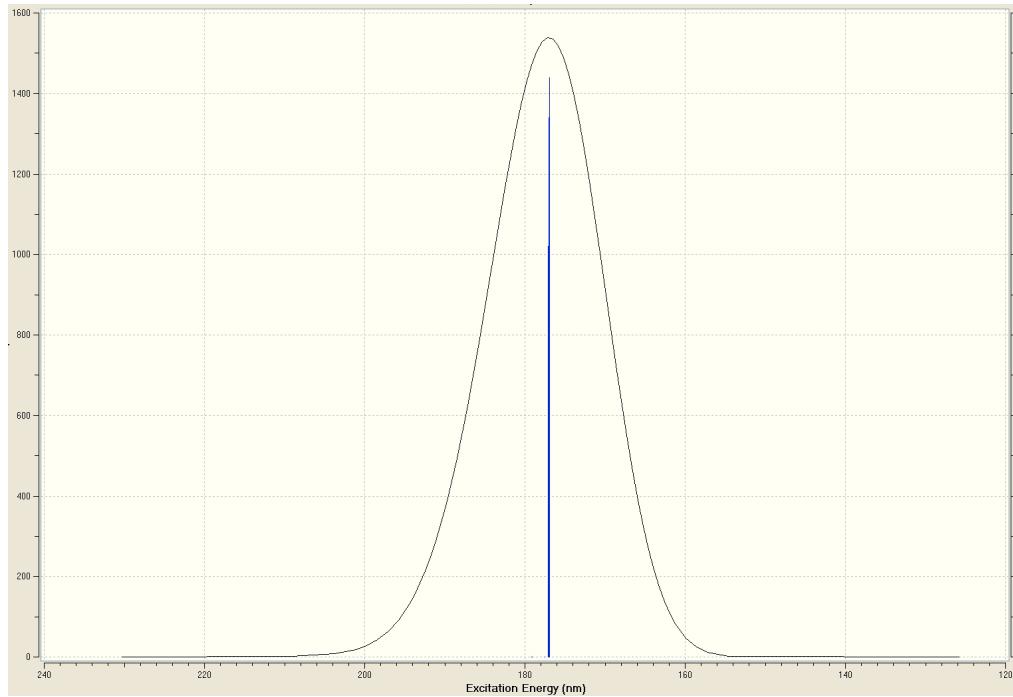

Figure 12. Oscillator strength as a function of excitation energy for 24-molecule (24H₂O) randomly-distributed water cluster calculated using TD-DFT.

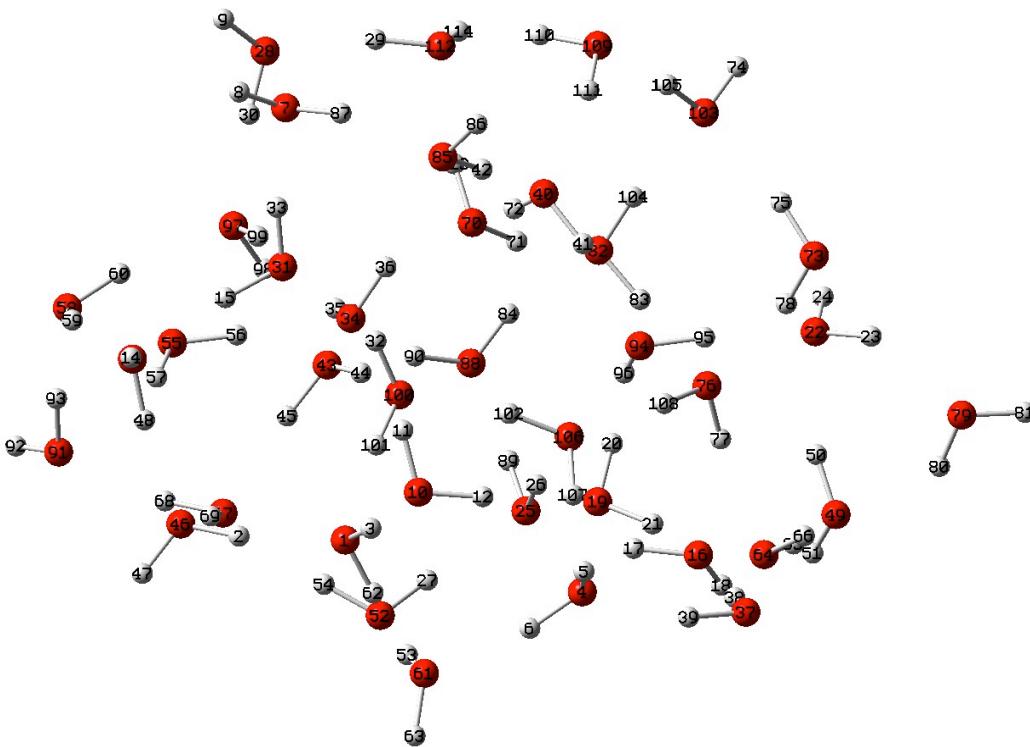

Figure 13. Molecular geometry of randomly-distributed water cluster consisting of 38 molecules, where relative location of atoms are given in Table 13.

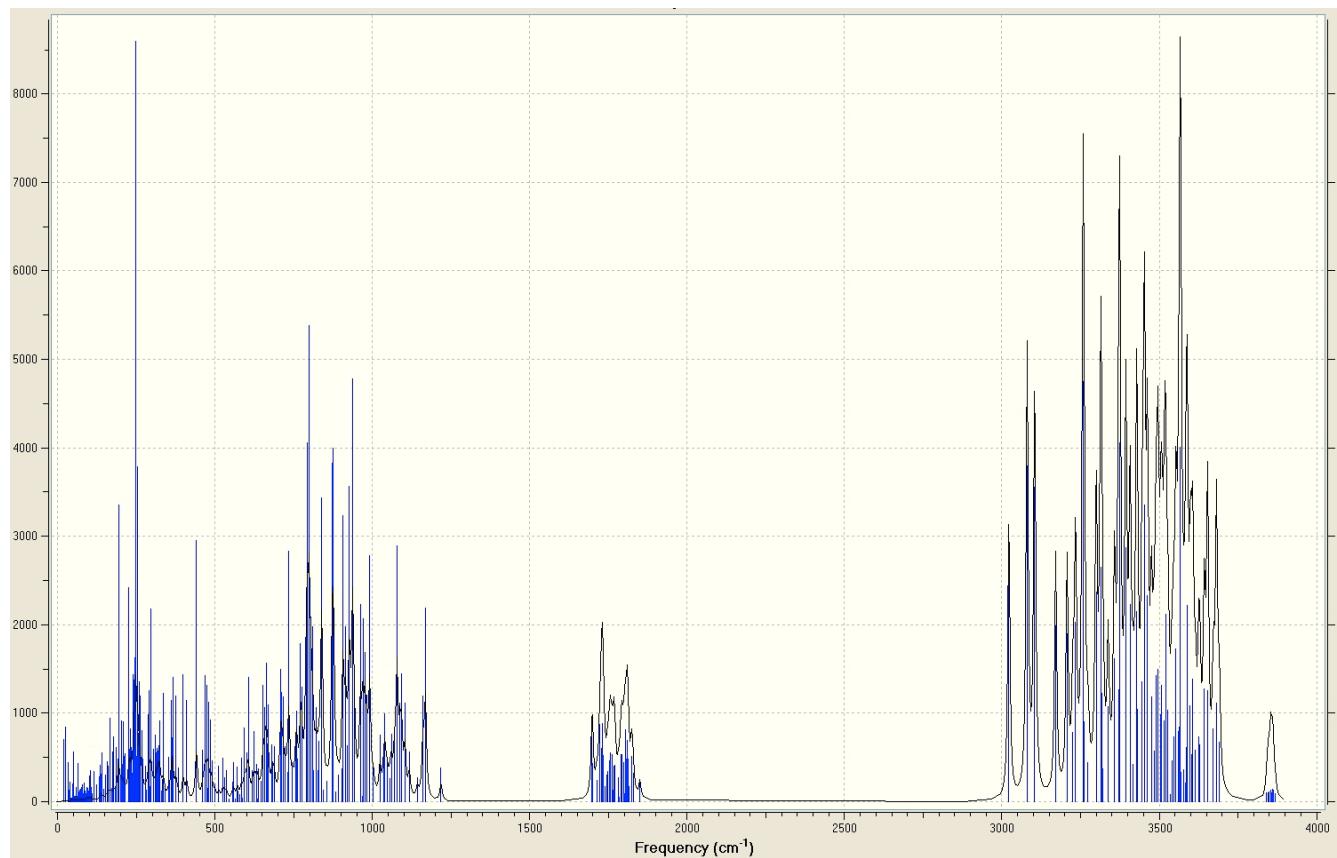

Figure 14. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for 38-molecule randomly-distributed water cluster according to frozen phonon approximation.

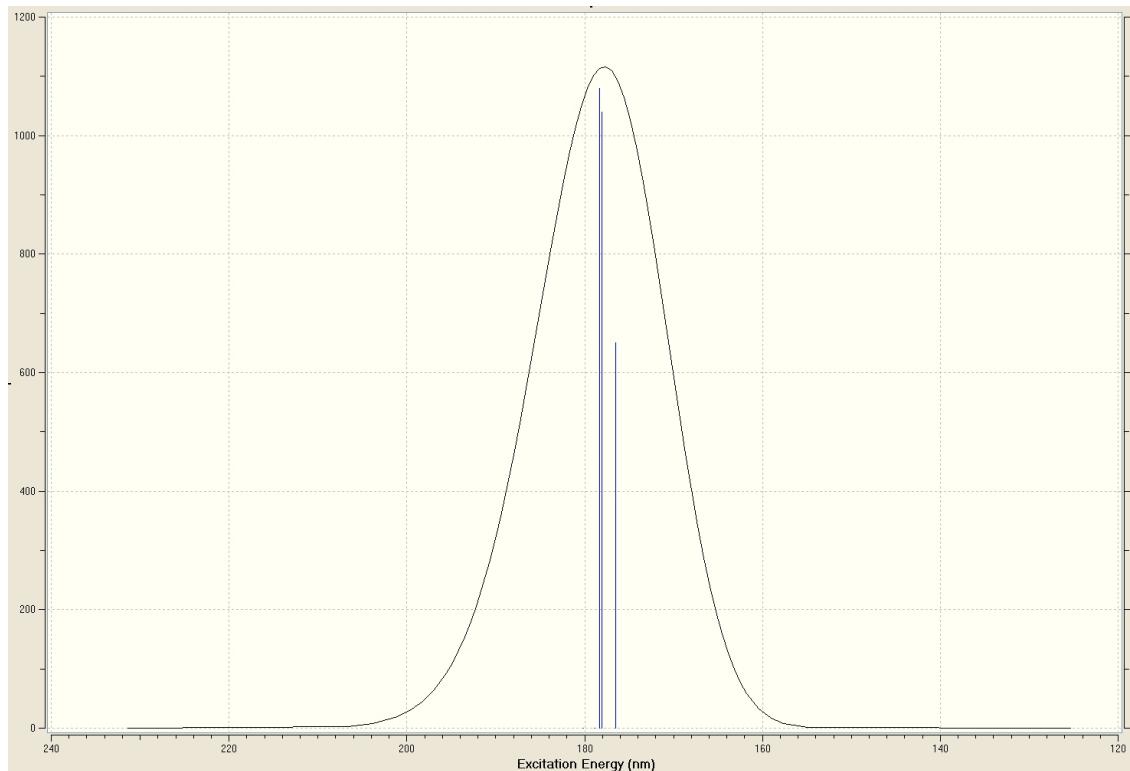

Figure 15. Oscillator strength as a function of excitation energy for 38-molecule ($38\text{H}_2\text{O}$) randomly-distributed water cluster calculated using TD-DFT.

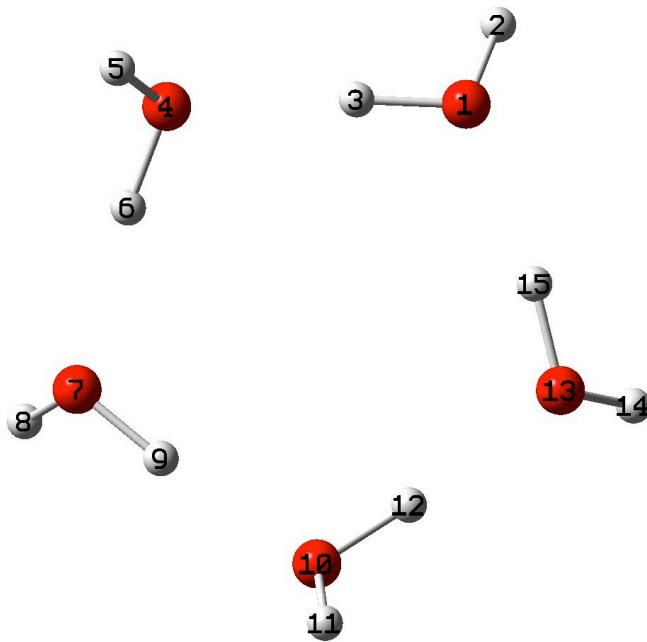

Figure 16. Molecular geometry of liquid-phase water cluster consisting of 5 molecules, where relative location of atoms are given in Table 16.

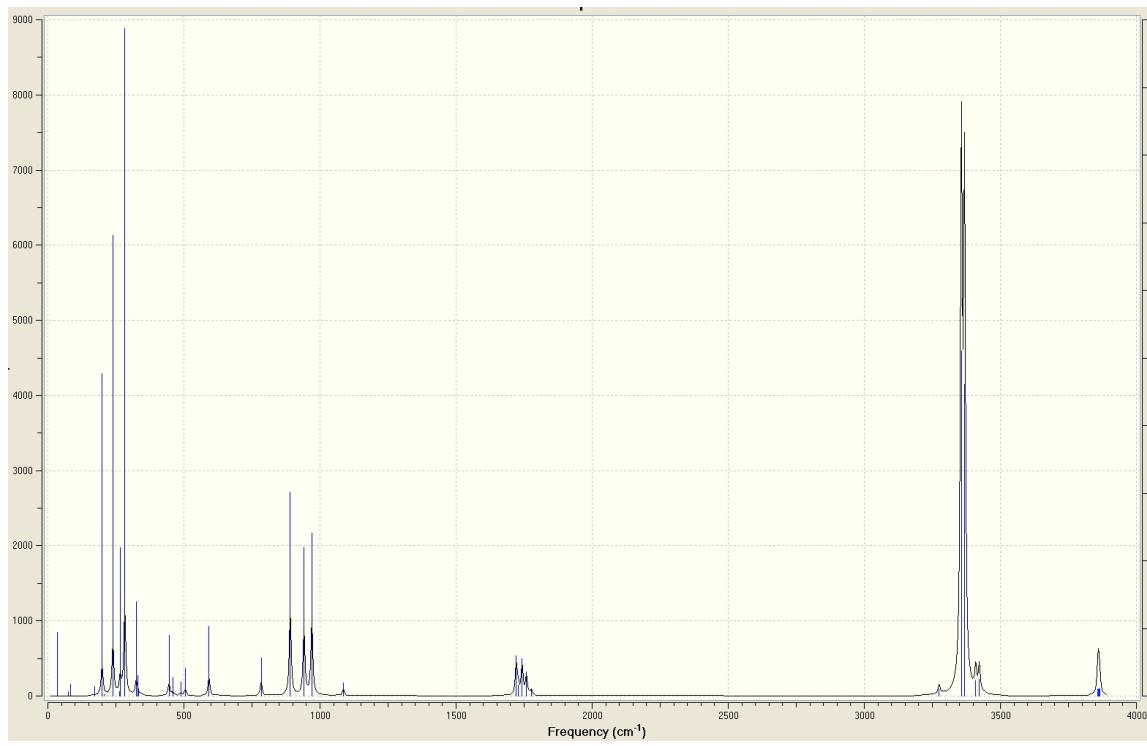

Figure 17. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for five-molecule liquid-phase water cluster according to frozen phonon approximation.

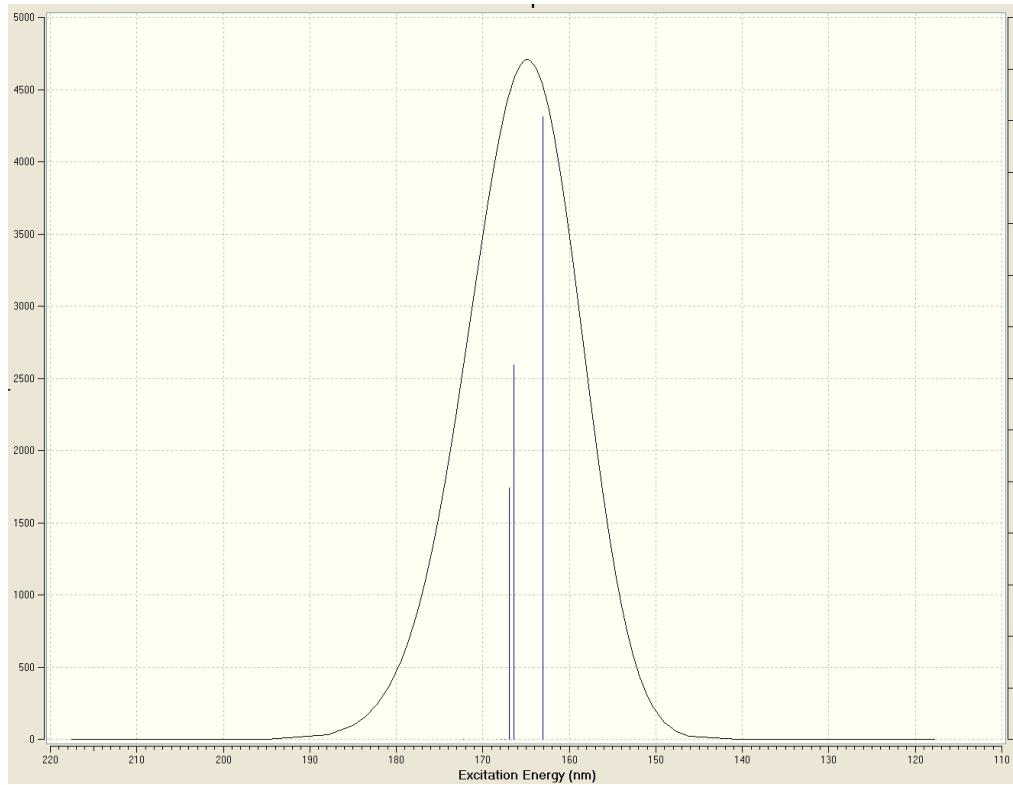

Figure 18. Oscillator strength as a function of excitation energy for five-molecule liquid-phase water cluster calculated using TD-DFT.

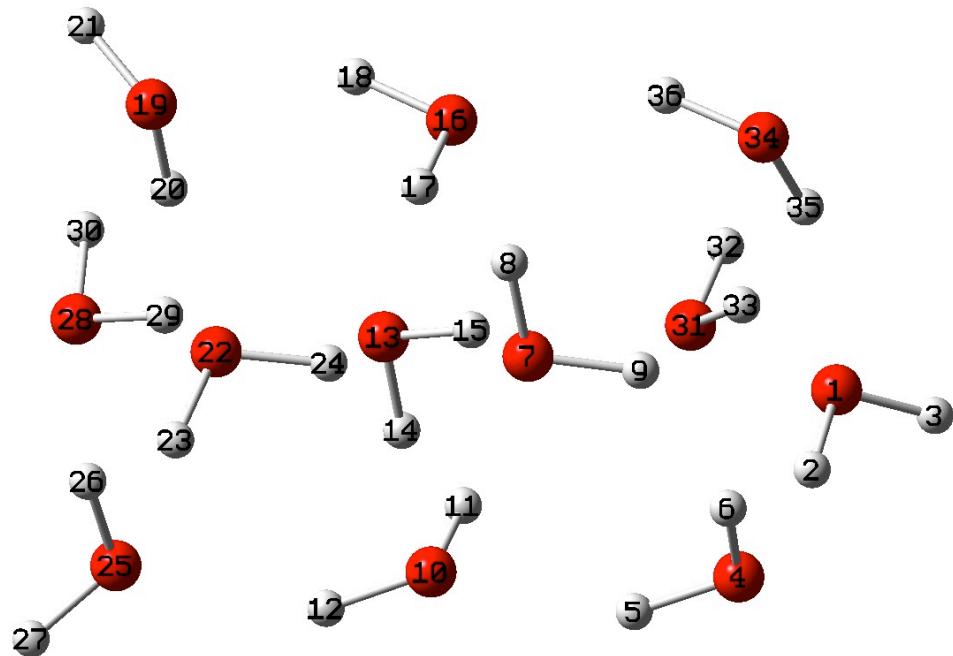

Figure 19. Molecular geometry of liquid-phase water cluster consisting of 12 molecules, where relative location of atoms are given in Table 19.

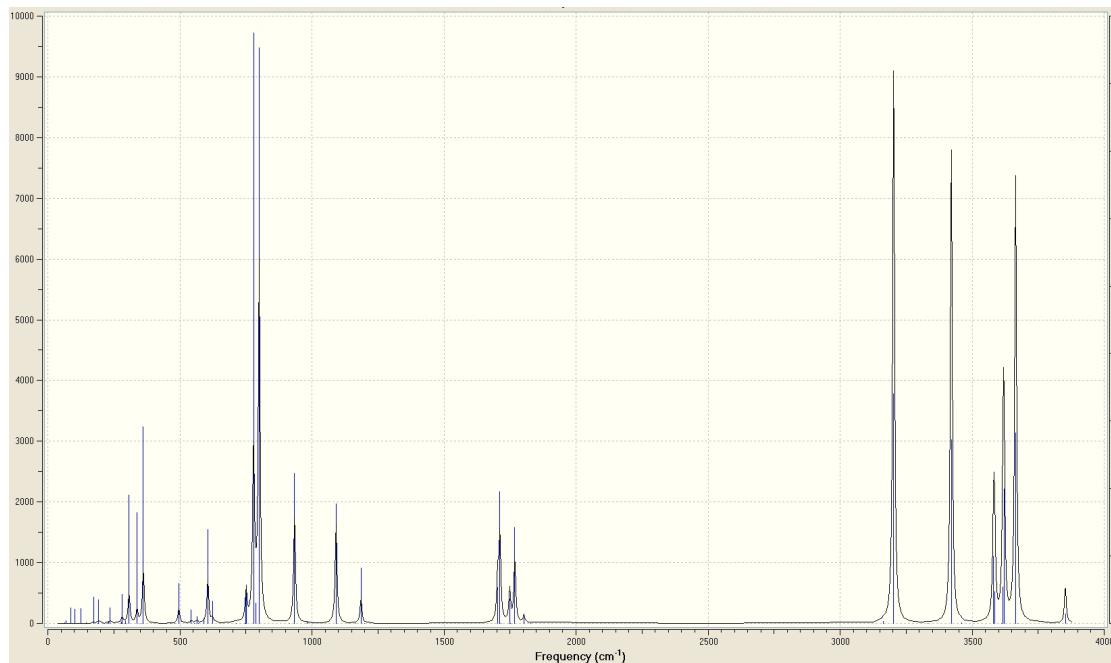

Figure 20. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for twelve-molecule liquid-phase water cluster according to frozen phonon approximation.

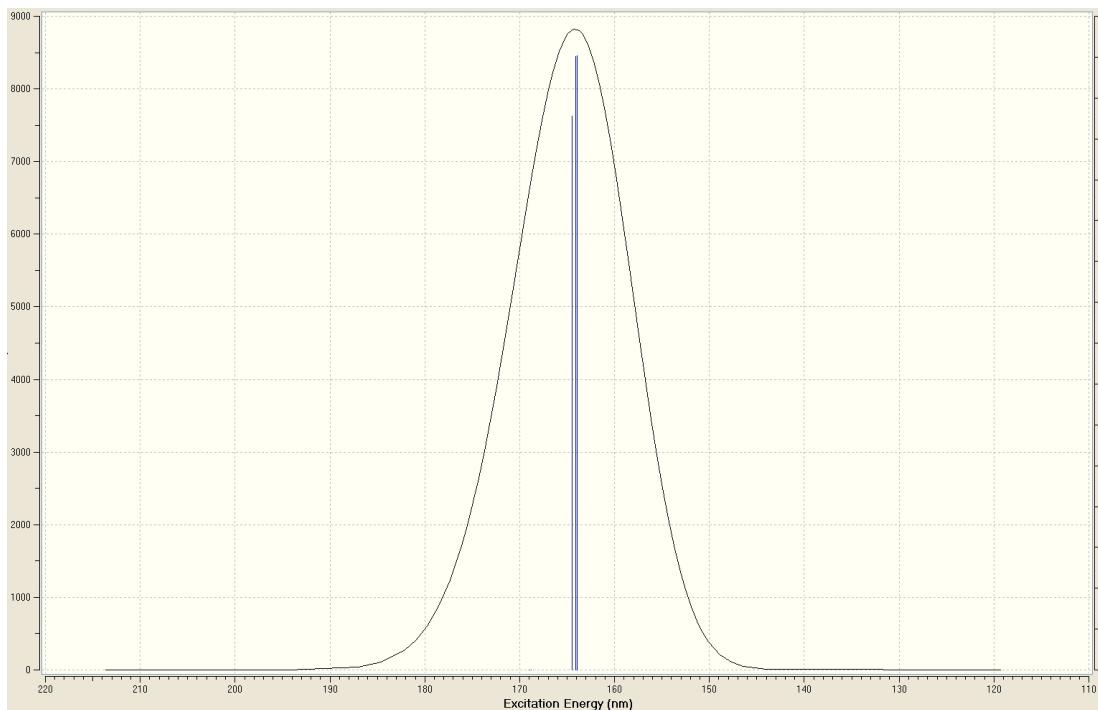

Figure 21. Oscillator strength as a function of excitation energy for 12-molecule ($12\text{H}_2\text{O}$) liquid-phase water cluster calculated using TD-DFT.

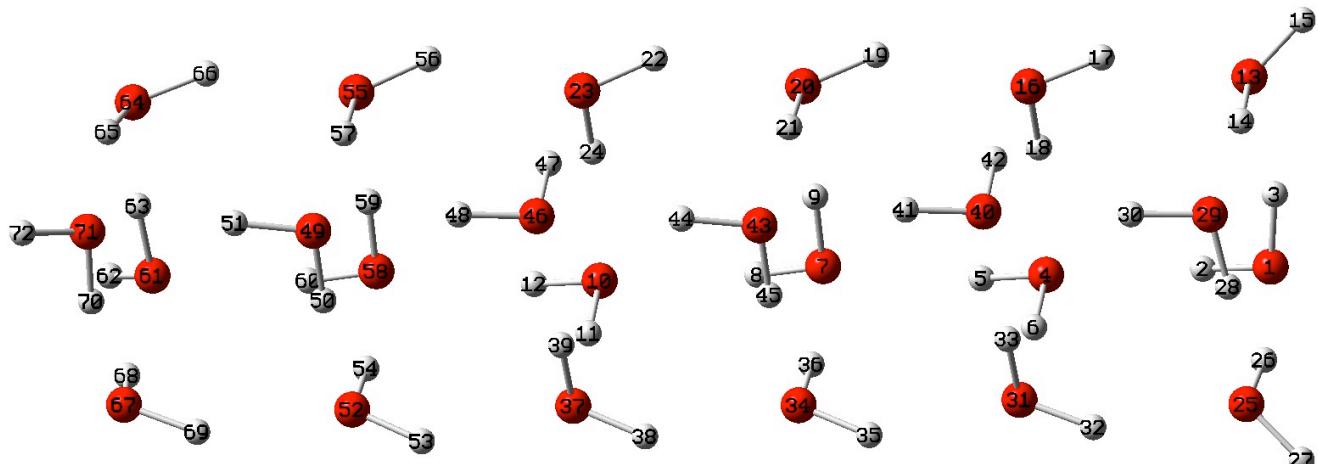

Figure 22. Molecular geometry of liquid-phase water cluster consisting of 24 molecules, where relative location of atoms are given in Table 22.

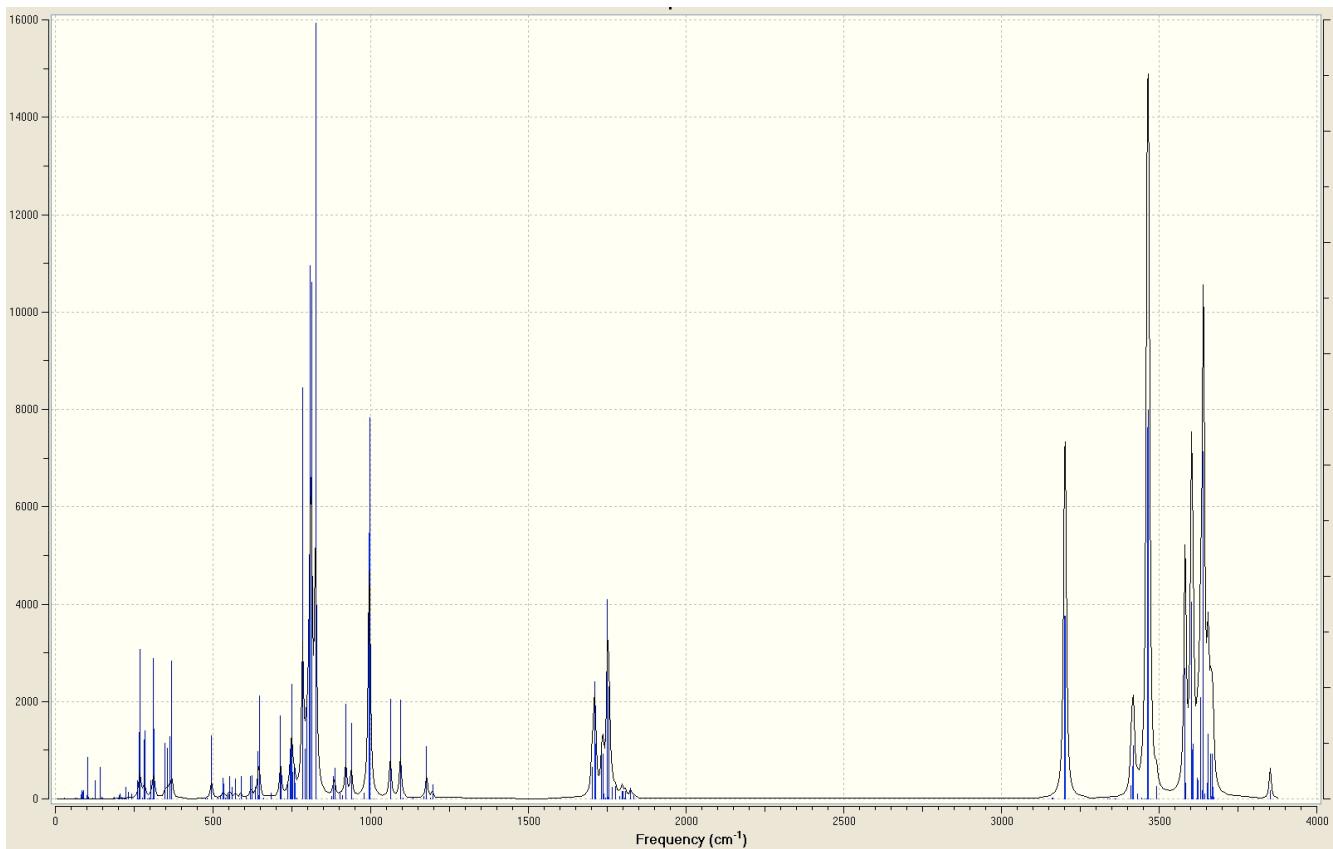

Figure 23. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for twenty-four-molecule ($24\text{H}_2\text{O}$) liquid-phase water cluster according to frozen phonon approximation.

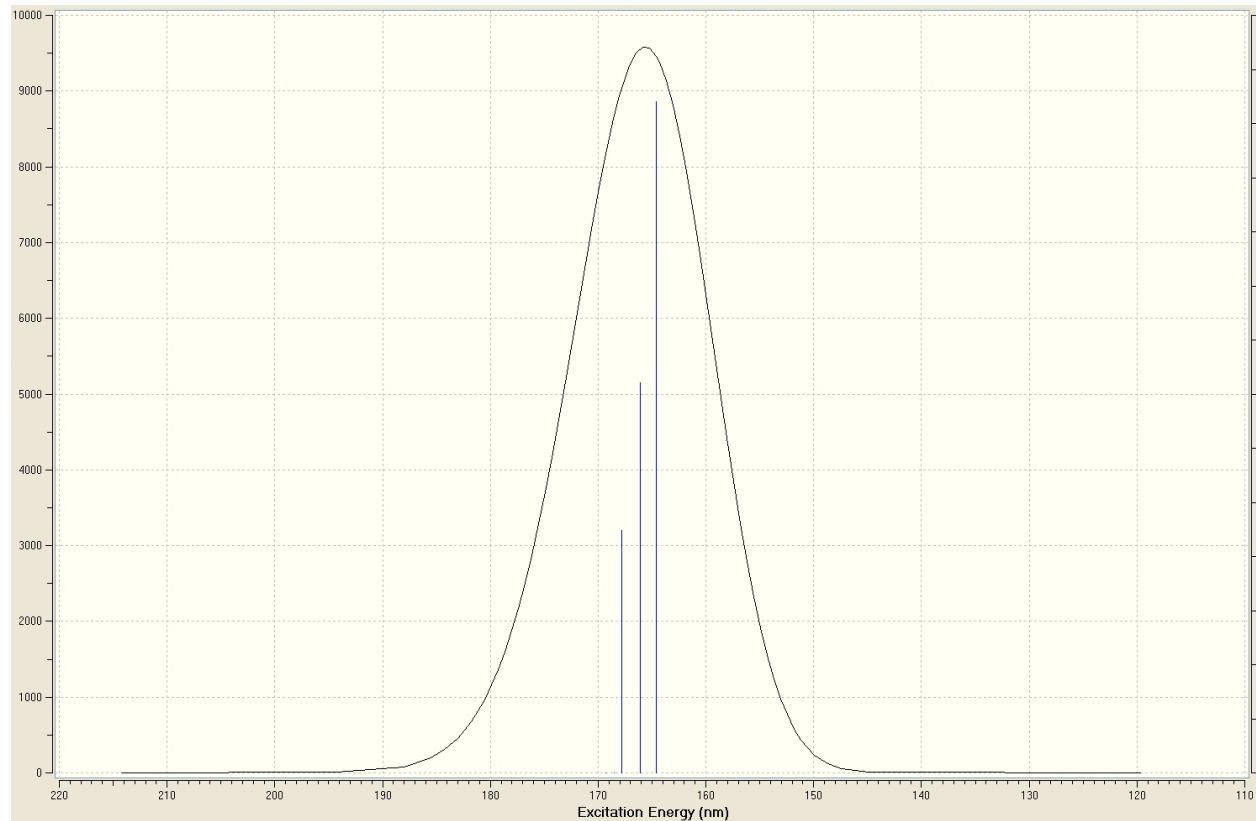

Figure 24. Oscillator strength as a function of excitation energy for 24-molecule liquid-phase water cluster calculated using TD-DFT.

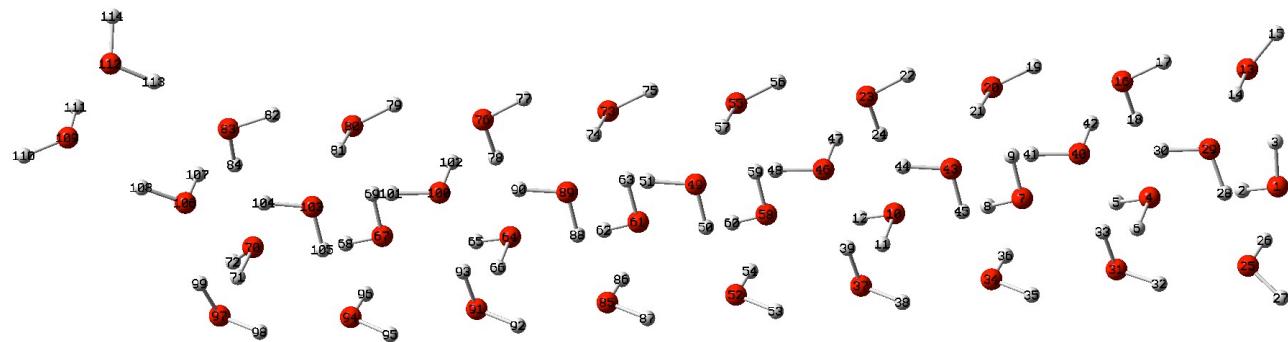

Figure 25. Molecular geometry of liquid-phase water cluster consisting of 38 molecules, where relative location of atoms are given in Table 25.

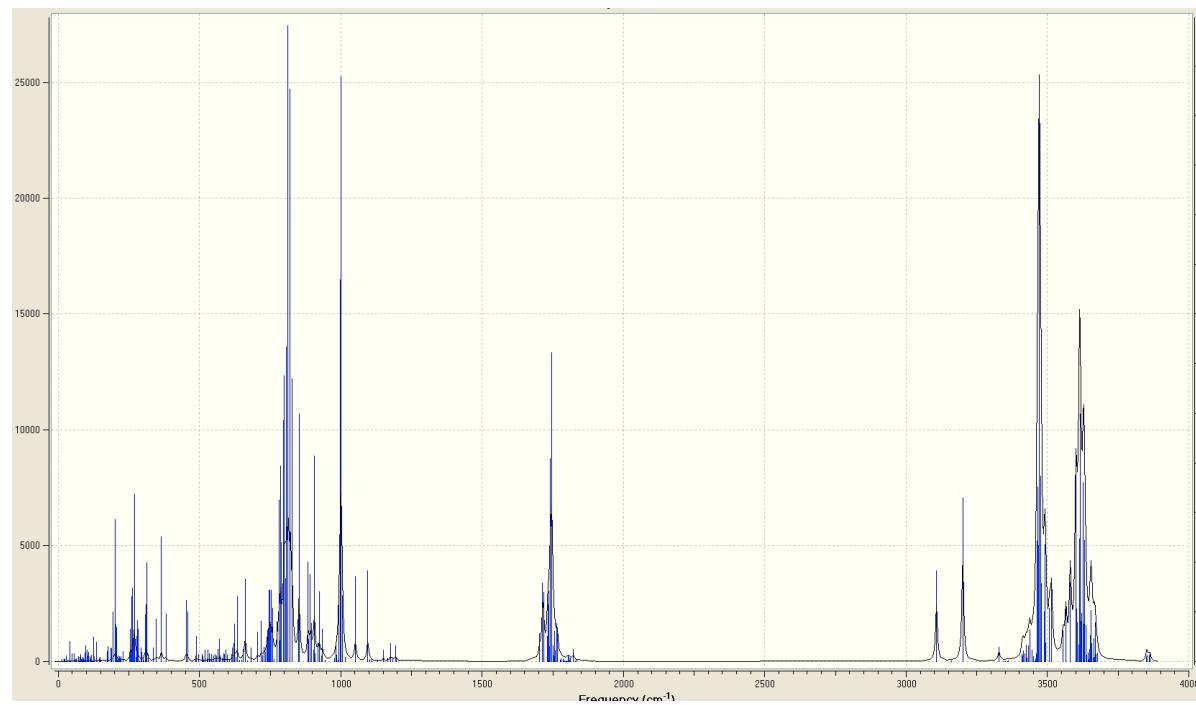

Figure 26. IR intensity as a function of frequency calculated using DFT B3LYP/6-311+G(d) for 38-molecule liquid-phase water cluster according to frozen phonon approximation.

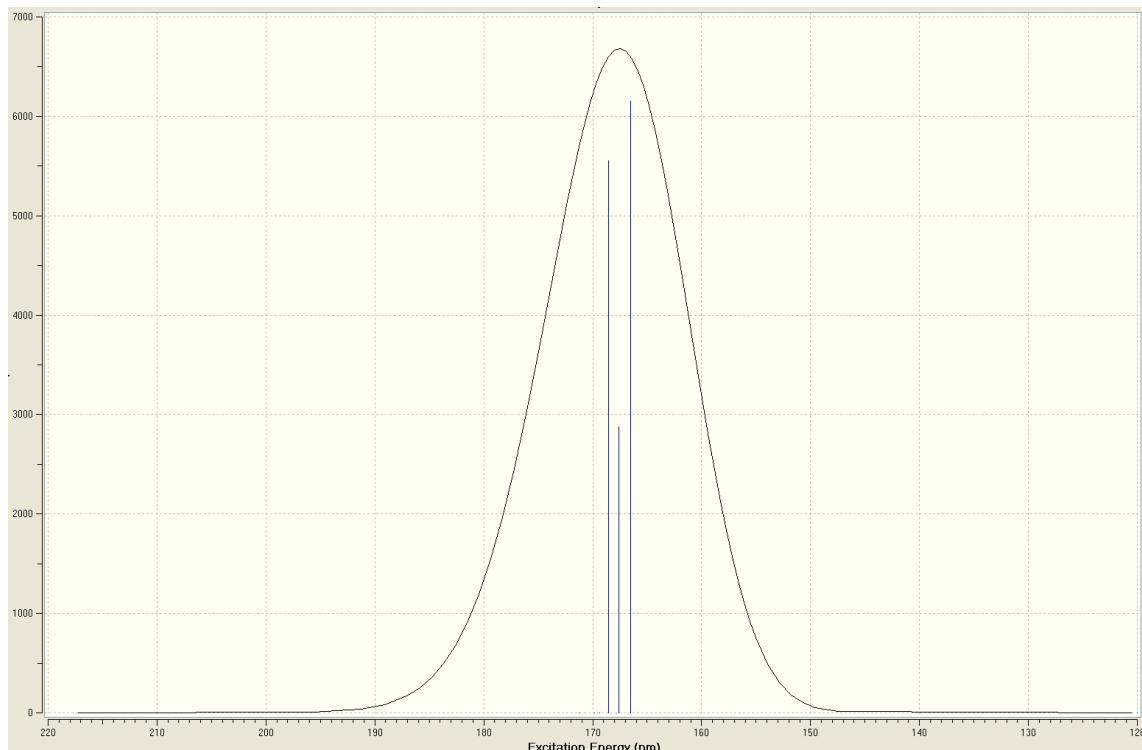

Figure 27. Oscillator strength as a function of excitation energy for 38-molecule liquid-phase water cluster calculated using TD-DFT.

Table 1. Atomic positions of two-molecule randomly-distributed water cluster after geometry optimization.

Center Number	Atomic Type	Coordinates (Å)			Center Number	Atomic Type	Coordinates (Å)
